INVESTIGATING DIFFUSION MOBILITY OF ZURCONIUM IN ZURCON-CONIUM-NIOBIUM ALLOYS

G. G. Ryabova and P. L. Grusin

Alloys of the zirccrium-niobium system arouse greater scientific and practical interest. In recent years the properties of alloys of this system have been investigated by many researchers. Zirconium alloys were found with small additions of niobium, alloys with properties, satisfactory for application of these alloys in the construction of reactors [1, 2], as well as alloys with higher niobium content, characterized by excellent fire and heat resistance [2,3]

Zirce ium and niobium - high melting metals. But zirconium, in spite of the high melting point, is distinguished by low heat reasistance. Niobium is characterized by good heat resistance qualities.

Investigation of diffusion characteristics in a system of alloys on the besis of these two metals is of interest for the purpose of explaining the diffusion mobility of atoms during change over from zirconium, having high diffusion mobility, to niobium, distinguished, judging by its heat resistance, by slow mobility of atoms.

To investigation diffusion of zirconium in zirconium-niobium alloys were melted alloys of the following niobium content (weight %): 1; 2; 3; 7; 20; 35; 70; 90 and 100. In role of basic material for the preparation of alloys was used iodide low-haf-nium zirconium and niobium, containing the following admixtures (weight %): Ta-1; C-0.09; Cr-0.1; 0-0.05; H = 0.003; N = 0.03.

The alloys were molted in an MIFI-9-3 type are furnace with tungsten electrode and water cooled crucible in an atmosphere of purified argon. For additional purification of furnace chamber from gases prior to melting the alloys the getter was melted several times. Uniform distribution of elements in the alloys was attained by repeated refounding (8-15 times) without disturbing the hermaticity of the formace.

Bars of casted alloys containing up to 20% of niobium were subjected to hor for ging in open air at a temperature of 900-700°C and to grinding to remove the layer of scales, and then cut into samples with a dimension of 3X8X15 nm. At a more than 20% niobium content in the alloy the samples were prepared from casted alloys.

The obtained samples were subjected to homogenizing annealing at 1200°C for a period of 10 hrs and at 1400°C for a period of 24 hours (alloys containing less than 20% niobium. Annealings at 1200°C were carried out in a quartz tube, pumped out to a pressure of 1:10° mm Hg, placing it in a tubular resistance furnace. Alloys with greater niobium content were annealed in a TVV-4 type furnace at a remanent pressure of 1:10°4 mm Hg.

After homogenizing annealing on the samples was a plied a layer of radioactive zirconium isotope $2r^{95}$ in a special vacuum installation. To the layer was tens of fractions of a micron. The thickness uniformly of the dusted on layer was checked by taking an autoradiogram from samples directly after the dusting on the radioactive isotope.

After the dusting on the samples, placed in pairs with the radioactive surface inward, we bound by a molybdemum wire and subjected to diffusion annealing in vacuum at corresponding temperatures. Together with the samples were wrapped in foil zirconium shavings, serveing as getter. In table 1 are given demonstrature and time of exposure of diffusion annealings of zirconium/niobium alloys.

Table 1. Data on temperature and duration of exposure of diffusion annealings of zirconium/niobium alloys

After the annualings the diffusion coefficients were letermined by the method of removing a layer and measuring the integral radioactivity of the remains of the sample, introduced by P.L.Gruzin[4].

In tables 2-4 are given experimentally found zirconium diffusion coefficients for the investigated alloys. On the basis of temperature dependence of diffusion coefficients were obtained activation energy values for zirconium diffusion and preex; one atial multiplier values corresponding to them (Table 2-4).

In fig.1 are given concentrational do indences of zirconium diffusion coefficients in alloys for temperatures of 2000, 1200 and 1600°C. It is evident from the graphs that the diffusion mobility of zirconium alloys changes in dependence upon the nicebium concentration in the alloys. Diffusion mobility of zirconium atoms decreases

gradually with a rise in michium up to 50%, and then follows a sharp drop in the diffusion coefficient magnitude. And so the coefficients of zirconium diffusion at 1200°C decrease by approximately one and one half orders in alloys from pure zirconium to an alloy with 50% zirconium and 50% niobium and by four powers in alloys with an up to 50% niobium content to pure niobium.

The structural diagram of zirconium/micbium alloys has a minimum along the solidus curve in the field of compositions of approximatly 20 to 30% micbium[3]. But
on the curce of the concentrational coefficients of diffusion on the side of zirco
nium a reduction inmelting point of the alloys is not accompanied by a rise in diffusion mobility of zirconium atoms. On the side of micbium with a reduction in the
melting point of the alloys the diffusion mobility of zirconium atoms increases.

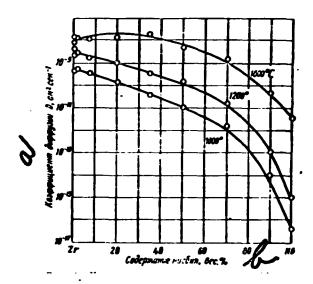

Fig.1. Concentrational dependence of diffusion coefficients of zirconium in zirconium/niobium alloys; a-diffusion coefficient; b-niobium content...

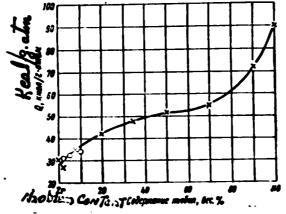

We have obtained results on the diffusion of miobium in zirconium. In connection with the absence of metallic artificial radioactive miobium isotope, Nb⁹⁵, we used in correspondents a miobium isotope in form of miobium conslate Nb⁹⁵. After this solution has been chemically processed on the samples was applied a layer of miobium conide, containing Nb⁹⁵. Consequently significances by with the diffusion of miobium

in zirconium, apparently, took place diffusion of oxygen, which might have exerted a certain influence on the diffusion of niobium in zirconium. Obtained data are listed in table 5. The coefficients of diffusion of niobium in zirconium are close in magnitude to the coefficients of autodiffusion of zirconium.

Table 5. Parameters of niobium diffusion in zirconium

Alloy	Diffusion at temp	coeffici eratures			
	1000	1100	1200	Do. cm²/cex	Kerlla atm
Zr	6,23 - 10-11	1,47-10-9	3,9 · 10 - •	2,2 · 10 →	

By comparing the coefficients of diffusion of zirconium in niobium and niobium in zirconium is evident, that, for example, for a temperature of 1200°C the diffusion coefficients differ by more than 6 magnitudes.

Calculation of zirconium diffusion coefficients for alloys showed, that at melting
points all alloys have a diffusion coefficient of the magnitude of 10⁻⁸ cm² sec⁻¹.

The melting point of alloys was taken on the
basis of the structural diagram of the
zirconium/niobium system[5].

The concentrational dependence of activa-

tion energy for zirconium diffusion is shown

Fig.2. Concentrational dependence of activation energy of zirconium diffusion in in fig.2. The activation energy of zirconium zirconium/niobium alloys: x-results of given experiment; • - results of experiments diffusion rises with the increase in nioby [6]
bium content in the alloys. A rise in diffusion

activation energy with simultaneous reduction of diffusion mobility in alloys indicates a strengthaning of the interatoric bond in the crystalline lattice of zirconium.

This is also confirmed by data about the change in elasticity mobiles of the alloys in the zirconium/niobium system, obtained by [5].

In the experiment [6] was examined the diffusion mobility of mirconium alloys with a miobium content of 2; 5; 10 percentages by weight. The activation energy values of mirconium diffusion in these alloys are plotted on graph fig.2. and are in conformity with values, obtained in the given experiment.

The mignitude of activation energy of zirconium alf-diffusion, obtained in the given experiment, equals 30.5 cal/g.atm. In other experiments [4,7,8] are given activation energy values for self-diffusion of zirconium, differing from the previous one. The discrepancy in activation energy values for self-diffusion of zirconium is connected, apparently, with the influence of the structural factor on diffusion mobility of zirconium. As result of alpha — beta-conversion of zirconium when heated in bota-phase crystals is retained a greater amount of intragramular separation surfaces, facilitating the occurrence of diffusion processes. We [8] as well as [7] should that the elimination of the effect of intragramular separation surfaces leads to a rise in activation energy for self-diffusion of zirconium to 38[7] and 47 kcal/g.stm[8].

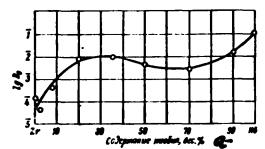

Fig.3. Concentrational dependence 1cDo for diffusion of zirconium in zirconium/niobium alleys. a - Niobium content.

In fig.3.is shown the concentrational dependence lgDo.calculated in accordance
with experimental data. Fordiffusion of zirconium in miobium the value Do=0.1 cm²/sec
appears to be conventional for metals. For
the diffusion of miobium in zirconium this
where equals 2.2.10⁻⁴ cm² sec⁻¹ as well as
for self-diffusion of zirconium (Do=10⁻⁴)

cm²sec⁻¹), vey small. It is evident from fig.3, that with the rise in miobium content in alloys the preexponential multiplier D₀ increases.

The obtained experimental data on the measurement of the diffusion coefficient of zirconium in zirconium-miobium alloys, activation energy of diffusion and preexponential multiplier showed, that all these values depend upon the concentration of elements in the alloys. With a rise in miobium content in zirconium alloys is obser-

ved an increase in activation energy value for the diffusion of zirconium Q and Do.

Simultaneously with these is observed a reduction in diffusion mobility of zirconium atoms.

In this way, in the zone of existence of continuous solid solutions in the zirconiumniobium system is observed a smooth change of all diffusion parameters of zirconium with a rise in niobium content.

Mobium alloying of zirconium hampers the occurrence of diffusion processes in zirconium, strengthens the force of the bond between atoms in the crystalline lattice.
With this, apparently, is connected the rise in heat resistance of zirconium in alloys
with niobium.
